More precisely, we carry out the following computations:

- We calculate the natural homomorphism $\mathrm{O}(L_-) \to \mathrm{O}(q_-)$, and obtain an upper bound for the index $[\mathrm{O}(L_+, \mathcal{P}_+) : \mathit{\Gamma}]$ by Proposition **??**. In fact, we calculate the exact value of this index except for the case $\gamma = (\varepsilon_{12}, 0)$.
- We compute the finite sets $\widetilde{\Xi}_\tau$ and Ξ_τ defined in (**??**) and (**??**).
- We confirm that $\mathcal{M}(D_0) = \widetilde{\mathcal{W}}(D_0)$ holds by showing that Ξ_τ satisfies condition **??** in Corollary **??**.
- We calculate a finite generating set of the subgroup $\Sigma_\varepsilon([\tau])$ of $\mathrm{Cen}(\cdot 0, \varepsilon)$, and compute the orbit decomposition of Ξ_τ under the action of $\Sigma_\varepsilon([\tau])$. Thus we obtain the $\mathrm{Stab}_{\mathit{\Gamma}}(D_0)$-orbits in $\mathcal{W}(D_0)$ by Remark **??**.
- For each $\mathrm{Stab}_{\mathit{\Gamma}}(D_0)$-orbit in $\mathcal{W}(D_0)$, we compute by Lemma **??** the fiber of $\mu \colon \widetilde{\mathcal{W}}(D_0) \to \mathcal{W}(D_0)$ over over a representative of the orbit.

The results are summarized in Table **??**.
